Review: What is a Likelihood?

Suppose we write down the joint distribution of our data (y_i, x_i) for i = 1, ..., n.

$$Pr(y_1,\ldots,y_n,x_1,\ldots,x_n;\theta)$$

If (y_i, x_i) are I.I.D then we can write this as:

$$Pr(y_1,\ldots,y_n,x_1,\ldots,x_n;\theta)=\prod_{i=1}^N Pr(y_i,x_i;\theta)\propto \prod_{i=1}^N Pr(y_i|x_i;\theta)=L(\mathbf{y}|\mathbf{x};\theta)$$

We call this $L(\mathbf{y}|\mathbf{x};\theta)$ the likelihood of the observed data.

1

MLE: Example

Consider a linear regression with $\varepsilon_i|X_i \sim N(0, \sigma^2)$

$$Y_{it} = X_i' \beta_i + \varepsilon_i$$

We've discussed the least squares estimator:

$$\widehat{\beta}_{ols} = \arg\min_{\beta} \sum_{i=1}^{N} (Y_i - X_i'\beta)^2$$

$$\widehat{\beta}_{ols} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$$

MLE: Example

If we know the distribution of ε_i we can construct a maximum likelihood estimator

$$(\widehat{\beta}_{MLE}, \widehat{\sigma}_{MLE}^2) = \arg\min_{\beta, \sigma^2} L(\beta, \sigma^2)$$

Where

$$L(\beta, \sigma^{2}) = \prod_{i=1}^{N} p(y_{i}|X_{i}, \beta, \sigma^{2})$$

$$= \prod_{i=1}^{N} \frac{1}{\sqrt{2\pi\sigma^{2}}} \exp\left[-\frac{1}{2\sigma^{2}}(y_{i} - X'_{i}\beta)^{2}\right]$$

$$\ell(\beta, \sigma^{2}) = \sum_{i=1}^{N} -\frac{1}{2} \ln(2\pi\sigma^{2}) - \frac{1}{2\sigma^{2}} \sum_{i=1}^{N} (y_{i} - X'_{i}\beta)^{2}$$

3

MLE: FOC's

Take the FOC's

$$\ell(\beta, \sigma^2) = -\frac{N}{2} \ln(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{i=1}^{N} (y_i - X_i'\beta)^2$$

Where

$$\frac{\partial \ell(\beta, \sigma^2)}{\partial \beta} = \frac{1}{\sigma^2} \sum_{i=1}^{N} (y_i - X_i' \beta) = 0 \rightarrow \widehat{\beta}_{MLE} = \widehat{\beta}_{OLS}$$

$$\frac{\partial \ell(\beta, \sigma^2)}{\partial \sigma^2} = -N \frac{1}{2\sigma^2} - \frac{1}{2\sigma^4} \sum_{i=1}^{N} (y_i - X_i' \beta)^2 = 0$$

$$\sigma_{MLE}^2 = \frac{1}{N} \sum_{i=1}^{N} (y_i - X_i' \beta)^2$$

Note: the unbiased estimator uses $\frac{1}{N-K-1}$.

MLE: General Case

- 1. Start with the joint density of the data Z_1, \ldots, Z_N with density $f_Z(z; \theta)$
- 2. Construct the likelhood function of the sample $z = (z_1, \dots, z_n)$

$$L(z;\theta) = \prod_{i=1}^{N} f_{Z}(z_{i};\theta)$$

3. Construct the log likelihood (this has the same arg max)

$$\ell(\mathbf{z};\theta) = \sum_{i=1}^{N} \ln f_{Z}(z_{i};\theta)$$

4. Take the FOC's to find $\widehat{\theta}_{MLE}$

$$\theta: \frac{\partial \ell(\theta)}{\partial \theta} = 0$$

5

MLE in Detail

Basic Setup: we know $F(z; \theta_0)$ but not θ_0 . We know $\theta_0 \in \Theta \subset \mathbb{R}^K$.

- Begin with a sample of z_i from i = 1, ..., N which are I.I.D. with CDF $F(z; \theta_0)$.
- The MLE chooses

$$\widehat{\theta}_{MLE} = \arg\max_{\theta} \ell(\theta) = \arg\max_{\theta} \sum_{i=1}^{N} \ln f_{Z}(z_{i}; \theta)$$

MLE: Technical Details

1. Consistency. When is it true that for $\epsilon > 0$?

$$\lim_{N\to\infty} \Pr\left(\left\|\hat{\theta}_{mle} - \theta_0\right\| > \varepsilon\right) = 0$$

2. Asymptotic Normality. What else do we need to show?

$$\sqrt{N}(\hat{\theta}_{mle} - \theta_0) \stackrel{d}{\longrightarrow} \mathcal{N}\left(0, -\left[E\frac{\partial^2}{\partial\theta\partial\theta'}(Z_i, \theta_0)\right]^{-1}\right)$$

3. Optimization. How to we obtain $\widehat{\theta}_{MLE}$ anyway?

MLE: Example # 1

• $Z_i \sim N(\theta_0, 1)$ and $\Theta = (-\infty, \infty)$. In this case:

$$\ell(\theta) = -N \cdot \ln(2\pi) - \sum_{i=1}^{N} (z_i - \theta)^2 / 2$$

- MLE is $\widehat{\theta}_{MLE} = \overline{z}$ which is consistent for $\theta_0 = E[Z_i]$
- Asymptotic distribution is $\sqrt{N}(\bar{z} \theta_0) \sim N(0, 1)$.
- Calculating mean is easy!

MLE: Example # 2

- $Z_i = (Y_i, X_i)$ X_i has finite mean and variance (but arbitrary distribution)
- $(Y_i|X_i=x) \sim N(x'\beta_0,\sigma_0^2)$

$$\widehat{\beta}_{MLE} = (X'X)^{-1}X'Y$$

$$\widehat{\sigma}_{MLE}^2 = \frac{1}{N}\sum (y_i - x_i\widehat{\beta}_{MLE})^2$$

 We already have shown consistency and AN for linear regression with normally distributed errors...

MLE: Example # 3

- $Z_i = (Y_i, X_i)$ X_i has finite mean and variance (but arbitrary distribution)
- $Pr(Y_i = 1 | X_i = x) = \frac{e^{x'\theta_0}}{1 + e^{x'\theta_0}}$
- Solution is the logit model.
- No simple MLE solution, establishing properties is not obvious...

Jensen's Inequality

Let g(z) be a convex function. Then $\mathbb{E}[g(Z)] \ge g(\mathbb{E}[Z])$, with equality only in the case of a linear function.

More Technical Details

Define Y as the ratio of the density at θ to the density at the true value θ_0 both evaluated at Z

$$Y = \frac{f_Z(Z;\theta)}{f_Z(Z;\theta_0)}$$

- Let $g(a) = -\ln(a)$ so that $g'(a) = \frac{-1}{a}$ and $g''(a) = \frac{1}{a^2}$.
- Then by Jensen's Inequality $\mathbb{E}[-\ln Y] \ge -\ln \mathbb{E}[Y]$.
- This gives us

$$\mathbb{E}_{z}\left[-\ln\left(\frac{f_{Z}(Z;\theta)}{f_{Z}(Z;\theta_{0})}\right)\right] \geq -\ln\left(\mathbb{E}_{z}\left[\frac{f_{Z}(Z;\theta)}{f_{Z}(Z;\theta_{0})}\right]\right)$$

The RHS is

$$\mathbb{E}_{z}\left[\frac{f_{Z}(Z;\theta)}{f_{Z}(Z;\theta_{0})}\right] = \int \frac{f_{Z}(z;\theta)}{f_{Z}(z;\theta_{0})} \cdot f_{Z}(z;\theta_{0}) dz = \int f_{Z}(z;\theta) dz = 1$$

More Technical Details

Because log(1) = 0 this implies:

$$\mathbb{E}_{z}\left[-\ln\left(\frac{f_{Z}(Z;\theta)}{f_{Z}(Z;\theta_{0})}\right)\right] \geq 0$$

Therefore

$$-\mathbb{E}\left[\ln f_Z(Z;\theta)\right] + \mathbb{E}\left[\ln f_Z(Z;\theta_0)\right] \ge 0$$

$$\mathbb{E}\left[\ln f_Z(Z;\theta_0)\right] \ge \mathbb{E}\left[\ln f_Z(Z;\theta)\right]$$

- We maximize the expected value of the log likelihood at the true value of θ !
- Helpful to work with $\mathbb{E}[\log f(z;\theta)]$ sometimes.

Information Matrix Equality

We can relate the Fisher Information to the Hessian of the log-likelihood

$$\mathcal{I}(\theta_{0}) = -\mathbb{E}\left[\frac{\partial^{2} \ln f}{\partial \theta \partial \theta}(z; \theta_{0})\right] = \mathbb{E}\left[\frac{\partial \ln f}{\partial \theta}(z; \theta_{0}) \times \frac{\partial \ln f}{\partial \theta}(z; \theta_{0})'\right]$$

- This is sometimes known as the outer product of scores.
- This matrix is negative definite
- Recall that $\mathbb{E}\left[\frac{\partial \ln f}{\partial \theta}(z;\theta_0)\right] \approx 0$ at the maximum

$$1 = \int_{z} f_{Z}(z; \theta) dz \Rightarrow 0 = \frac{\partial}{\partial \theta} \int_{z} f_{Z}(z; \theta) dz$$

With some regularity conditions

$$0 = \int_{z} \frac{\partial f_{Z}}{\partial \theta}(z; \theta) dz = \underbrace{\int_{z} \frac{\partial \ln f_{Z}}{\partial \theta}(z; \theta) \cdot f_{Z}(z; \theta) dz}_{\mathbb{E}\left[\frac{\partial \ln f_{Z}}{\partial \theta}(z; \theta_{0})\right]}$$

- This gives us the FOC we needed.
- Can get information identity with another set of derivatives.

The Cramer-Rao Bound

We can relate the Fisher Information to the Hessian of the log-likelihood

$$\mathcal{I}(\theta) = -\mathbb{E}\left[\frac{\partial^2 \ln f}{\partial \theta \partial \theta'}(Z; \theta)\right]$$

It turns out this provides a bound on the variance

$$Var(\hat{\theta}(Z)) \ge \mathcal{I}(\theta_0)^{-1}$$

Because we can't do better than Fisher Information we know that MLE is most efficient estimator!

MLE: Discussion

Tradeoffs

- How does this compare to GM Theorem?
- If MLE is most efficient estimate, why ever use something else?

Thanks!
